## Chapter 9: How can I tell if scores differ between three or more groups? One-way independent measures ANOVA.

## Full answers to study questions

1. Familywise error as a result of conducting multiple $t$ tests.
1.1. There are four categories, so six $t$ tests would be needed.
2. blonde vs. brown
3. blonde vs. black
4. blonde vs. auburn
5. brown vs. black
6. brown vs. auburn
7. black vs. auburn
1.2. There would be seven decade categories: $20 \mathrm{~s}, 30 \mathrm{~s}, 40 \mathrm{~s}, 50 \mathrm{~s}, 60 \mathrm{~s}, 70 \mathrm{~s}$ and 80 s . Therefore $21 t$ tests would be needed.
8. 20 s vs. 30 s
9. 20 s vs. 40 s
10. 20 s vs. 50 s
11. 20 s vs. 60 s
12. 20 s vs. 70 s
13. 20 s vs. 80 s
14. 30 s vs. 40 s
15. 30 s vs. 50 s
16. 30 s vs. 60 s
17. 30 s vs. 70 s
18. 30 s vs. 80 s
19. 40 s vs. 50 s
20. 40 s vs. 60 s
21. 40 s vs. 70 s
22. 40 s vs. 80 s
23. 50 s vs. 60 s
24. 50 s vs. 70 s
25. 50 s vs. 80 s
26. 60 s vs. 70 s
27. 60 s vs. 80 s
28. 70 s vs. 80 s
1.3. There are five categories, so $10 t$ tests would be needed.
29. plain vs. horizontal
30. plain vs. vertical
31. plain vs. diagonal
32. plain vs. checkered
33. horizontal vs. vertical
34. horizontal vs. diagonal
35. horizontal vs. checkered
36. vertical vs. diagonal
37. vertical vs. checkered
38. diagonal vs. checkered
39. The df for between, total and error are shown below. Full calculations are in the online resources.
2.1. $d f_{\text {between }}=3, d f_{\text {total }}=47, d f_{\text {error }}=44$

- $d f_{\text {between }}=4-1, d f_{\text {total }}=48-1, d f_{\text {error }}=47-3$
2.2. $d f_{\text {between }}=2, d f_{\text {total }}=74, d f_{\text {error }}=72$
- $d f_{\text {between }}=3-1, d f_{\text {total }}=75-1, d f_{\text {error }}=74-2$
2.3. $d f_{\text {between }}=4, d f_{\text {total }}=44, d f_{\text {error }}=40$
- $d f_{\text {between }}=5-1, d f_{\text {total }}=45-1, d f_{\text {error }}=44-4$

3. Results given in full and with interpretation of significance.
3.1. $F(2,36)=8.6, p<.001$, a significant finding.
3.2. $F(3,11)=4.2, p<.050$, a significant finding.
3.3. $F(4,24)=4.9, p<.010$, a significant finding.

## Full answers for additional dataset

1. What method of analysis will you use to analyse this dataset?

A one-way independent measures ANOVA. The IV is the food eaten, with three independent conditions: nothing, chocolate or chilli crisps. The DV is agreeableness.
2. Suggest a suitable hypothesis for this analysis.

Agreeableness scores will differ significantly depending on the type of food eaten. (Note, this is a twotailed hypothesis).
3. Calculate the $F$ ratio and determine whether it is significant.

Note: The step numbers for calculations in the book chapter are repeated here.

|  | Nothing |  | Chocolate |  | Chilli crisps |  |
| :---: | :---: | :---: | :---: | :---: | :---: | :---: |
|  | Score $(x)$ | Squared $\left(x^{2}\right)$ | Score $(x)$ | Squared $\left(x^{2}\right)$ | Score $(x)$ | Squared $\left(x^{2}\right)$ |
|  | 6 | 36 | 12 | 144 | 2 | 4 |
|  | 7 | 49 | 10 | 100 | 8 | 64 |
|  | 8 | 64 | 8 | 64 | 6 | 36 |
|  | 5 | 25 | 11 | 121 | 4 | 16 |
|  | 4 | 16 | 12 | 144 | 12 | 144 |
|  | 7 | 49 | 7 | 49 | 8 | 64 |
|  | 9 | 81 | 9 | 81 | 5 | 25 |
|  | 5 | 25 | 10 | 100 | 10 | 100 |
| Totals (T) | 51 | 345 | 79 | 803 | 55 | 453 |
| Square of totals ( $T^{2}$ ) | 2601 |  | 6241 |  | 3025 |  |
| Mean ( $\bar{x}$ ) | 6.38 |  | 9.88 |  | 6.88 |  |
| Standard deviation (SD) | 1.69 |  | 1.81 |  | 3.27 |  |

6: $\sum T^{2}=2601+6241+3025$
$\sum T^{2}=11867$

7: $\left(\sum x\right)^{2}=(51+79+55)^{2}$
$\left(\sum x\right)^{2}=185^{2}$
$\left(\sum x\right)^{2}=34225$

8: $\sum x^{2}=345+803+453$
$\sum x^{2}=1601$

Stage One: Calculate the Sums of Squares (SS)

9: $\mathrm{SS}_{\text {between }}=\frac{11867}{8}-\frac{34225}{24}$

$$
\begin{aligned}
& \mathrm{SS}_{\text {between }}=1483.375-1426.042 \\
& \mathrm{SS}_{\text {between }}=57.333 \\
& 10: \mathrm{SS}_{\text {total }}=1601-\frac{34225}{24}
\end{aligned}
$$

$$
S S_{\text {total }}=1601-1426.042
$$

$$
\mathrm{SS}_{\text {total }}=174.958
$$

11: $S S_{\text {error }}=174.958-57.333$

$$
S S_{\text {error }}=117.625
$$

Stage Two: Calculate the degrees of freedom (df)

12: $d f_{\text {between }}=3-1$

$$
d f_{\text {between }}=2
$$

13: $d f_{\text {total }}=24-1$

$$
d f_{\text {total }}=23
$$

14: $d f_{\text {error }}=23-2$

$$
d f_{\text {error }}=21
$$

Stage Three: Calculate the Mean Squares (MS)

15: $M S_{\text {between }}=57.333 / 2$

$$
M S_{\text {between }}=28.667
$$

16: $M S_{\text {error }}=117.625 / 21$

$$
M S_{\text {error }}=5.601
$$

Stage Four: Calculate the $F$ ratio
$17: F=28.667 / 5.601$ $F=5.118$

## ANOVA summary table

Using the values you have calculated, complete this ANOVA summary table.

|  | Sums of Squares <br> (SS) | Degrees of <br> Freedom (df) | Mean Squares <br> (MS) | F ratio |
| :---: | :---: | :---: | :---: | :---: |
| Between groups <br> variance | 57.3 | 2 | 28.7 | 5.1 |
| Within groups error <br> variance | 117.6 | 21 | 5.6 |  |
| Total variance in the <br> dataset | 175.0 | 23 |  |  |

4. Interpret and write up your findings using APA standards.

There was a significant main effect of type of food eaten ( $F(2,21$ ) $=5.12, p<.050$ ). Agreeableness was highest in the chocolate condition ( $M=9.88, S D=1.81$ ), lower in the chilli crisps condition ( $M=6.88$, $S D=3.27$ ) and slightly lower in the control condition ( $M=6.38, S D=1.69$ ).
5. There is far more variability in one of the conditions than in the other two. Which condition has the greatest amount of error variance and suggest reasons why this might be? Suggest three measureable variables that might account for some of this error variance.

There is far more variability in the chilli crisps condition, suggesting that agreeableness scores of participants in this condition were far more wide-ranging. There are a few reasons why this might be, but you could measure how much participants report liking crisps (those who dislike crisps might have lower scores), how spicy they tend to like their food (those who like very spicy food might have higher scores) or whether they are currently on a diet (being made to eat chocolate or crisps while on a diet may make people feel less agreeable).

Are p values enough? An optional exercise

$$
\begin{gathered}
\eta_{p}^{2}=\frac{57.3}{57.3+117.6} \\
\eta_{p}{ }^{2}=\frac{57.3}{174.9}
\end{gathered}
$$

$$
\eta_{p}^{2}=0.3276
$$

There was a significant main effect of type of food eaten $\left(F(2,21)=5.12, p<.050 ; \eta_{p}{ }^{2}=.33\right)$ with a large effect size. Agreeableness was highest in the chocolate condition ( $M=9.88, S D=1.81$ ), lower in the chilli crisps condition ( $M=6.88, S D=3.27$ ) and slightly lower in the control condition ( $M=6.38, S D=1.69$ ).
